Doyle-Scribner rule is extensively used for hardwoods, combining Scribner figures for 28 inches diameter and over with Doyle figures for smaller logs. The upper portion of the Scribner rule is therefore appended. Cut-off in upper table is shown by black cross rule.

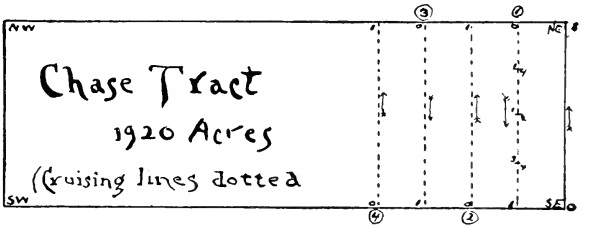
Timber Cruising

This diagram represents the tract of land to be cruised; the boundary lines are all plain, the corner posts up and plainly marked. Start at S. E. corner of tract (which will be O) follow boundary line to N. E. corner, estimating 4 rods on left side of line (in case



undergrowth is too dense to see that distance, take 2 rods). On arriving at N. E. corner, after estimating and chaining the distance, set up and mark stake at corner, with distance from the S. base line and name of estimator. From this corner, chain along the N. boundary line 20 chains (or ¼ mile); at this point, which will be line number 1, or line between sections 1 and 2, mark and set up stake with distance from corner, number of line or section, name of estimator, with → pointing direction taken from this point. It is always a good plan while chaining your cruising line to mark your ¼, ½, ¾ and 1 mile points, as they may come in handy later. Continue this every ¼ or ½ mile or whatever distance apart you have decided to run your cruising lines, until the whole tract is gone over.

The sample pages are the estimates, distances, notes and sketches made on line number 1, ¼ mile from and parallel to E. boundary line.

72224

In writing in your notes and sketches, begin at the bottom of

D. H. HILL LIBRARY
North Carolina State College

page and work along the line the way you are traveling, At whatever point on your line the change of growth occurs, draw a line across, showing its location, and in your partial and total chain columns, place your distance opposite line drawn.

The different species of trees to be estimated are placed in columns as shown. The estimate or scale of each log is kept on a separate tally sheet. At the end of each mile the scale of the different species is added and these amounts are placed in their respective columns on opposite page to your notes. After the tally leaf has been used it may be torn out and destroyed, or it may remain, providing the precaution is taken to mark or check the page to prevent its being copied again into your work by mistake.

This book may be used for the square and circle methods of estimating as well as the strip, using 2100 steps of ordinary length to the mile.

Most standing timber is estimated at sight and the length of log and diameter at top end determines scale or number of feet in the log. Among the many log rules in use in this country the Doyle seems to be the favorite, except in the northern states where the rule accepted by the state is largely used.

In estimating standing timber the length of log and diameter at small end, under bark, is a matter of good judgment coupled with a good eye and years of experience in cutting and scaling logs. When one has acquired this knowledge the experienced estimator's eye seeks the length instantly and at the same time determines the diameter.

In determining diameter, use 8-10-12-14-16, etc., inches, leaving out the odd inches as the even ones are close enough. Should a log be a little large for a 12″ and not quite a 14,″ call it a 12″ and even it up on a small 12″ later. The whole thing is a matter of experience and a thorough knowledge of cutting and the manufacture of logs.

Many lumber companies have a standard length of log, usually 16 feet. To meet such cases the 16-foot column in the tables on page 2 are distinguished by a black rule on either side of column so that it may be more conveniently located.

SOIL

In judging soil, fairly accurate work may be done by noting growth which the soil supports.

Maple, oak, red gum denote rich clay, very little sand if any.

Poplar, birch and mixed growth of bushes show more sand, not so much loam.

Pine denotes sandy, porous soil which is usually of poor quality.

Elm, brown or black ash, indicate deep, rich soil.

LUMBER MEASURE

Lumber is generally bought and sold by board measure. The unit of board measure is the board foot—a foot square and an inch thick. A board 18 feet long, 9 inches wide and 1 inch thick containes 13½ board feet. $9 \times 18 = 162$. $162 \div 12 = 13\frac{1}{2}$ board feet.

TIMBER MEASURE

Timber squared is usually sold by the cubic foot. Example: A stick of timber 16 ft. long, 10 in. wide and 8 in. thick contains $8\frac{8}{9}$ cu. ft. $8 \times 10 \times 16 \div 144 = 8\frac{8}{9}$.

One-half of the sum of the end diameters of a log, excluding the thickness of the bark, is called its mean diameter.

The number of board feet of square edged inch boards that can be sawed from a log 30 ft. long and 24 in. in diameter is 750 feet. Example: $24-4=20^2=400 \div 16=25$. $25 \times 30=750$ ft. Diameter used, mean, the diameter at middle of log. A board foot is $\frac{1}{12}$ of a cu. ft.

SURVEYORS' MEASURE

TABLE

7.92 inches = 1 link.
100 links = 1 chain.
80 chains = 1 statute mile.

1 chain = 4 rods = 22 yds. = 66 ft. = 792 inches.

A pace = 2½ ft. in ordinary walking, but 3.3 ft., or $\frac{1}{5}$ of a rod in stepping distances.

LINEAR MEASURE

Table

12 inches = 1 foot.
3 feet = 1 yard.
5½ yards = 1 rod.
320 rods = 1 statute mile.

1 mile = 320 rds. = 1760 yds. = 5280 feet.
40 rds. = 1 furlong, which is seldom used.
The geographic mile or knot = 6086 feet.
A fathom = 6 feet.

SQUARE MEASURE

The unit of land measure is the acre. It may be of any shape, but it is equivalent to a rectangular tract, 5 chains or 20 rds. long and 2 chains or 8 rds. wide.

Table

1000 sq. links } = 1 sq. chain.
16 sq. rds. }

10 sq. chains } = 1 acre.
160 sq. rds. }

640 acres = 1 sq. mile.

A square rod is also called a perch.

A sq. foot is 12 inches long, 12 inches wide = 12×12 = 144 sq. in. = 1 sq. foot.

A sq. yard is 3 feet × 3 feet = 9 sq. ft. = 1 sq. yd.

A sq. rod is 5½ yds. × 5½ yds. = 30¼ sq. yds. = 1 sq. rd.

CUBIC MEASURE

Table

1728 cu. inches = 1 cu. foot.
27 cu. feet = 1 cu. yard.

WOOD MEASURE

The unit of wood measure is the cord. It is a rectangular solid 8 ft. long, 4 ft. high and 4 ft. wide.

A cord foot is 1 ft. long, 4 ft. high and 4 ft. wide.

TABLE

128 cubic ft. = 1 cord.
16 cubic ft. = 1 cord foot.
8 cord ft. = 1 cord.

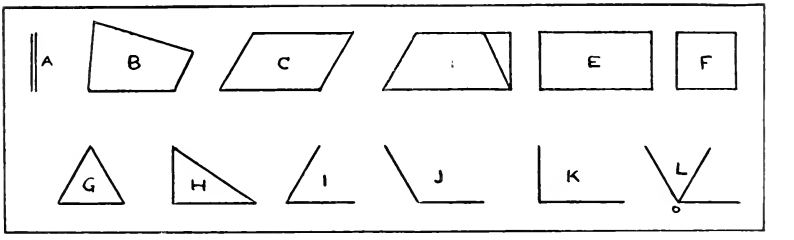
ANGULAR MEASURE

An angle equal to $\frac{1}{90}$ of a right angle is an angle of 1 degree, which is the unit of angles.

$\frac{1}{60}$ of an angle of 1 degree is an angle of 1 minute and $\frac{1}{60}$ of an angle of 1 minute is an angle of 1 second.

TABLE

60 seconds = 1 minute.
60 minutes = 1 degree.
90 degrees = 1 right angle ∟.



Parallel lines are straight lines at any distance from each other which remain at that distance, however far projected in either direction (Fig. A).

A quadrilateral is any figure bounded by four straight lines (Figs. B to F inclusive).

A parallelogram is a quadrilateral whose opposite sides are parallel (Figs. C, E and F).

A trapezoid is a quadrilateral, only two of whose opposite sides are parallel (as per Fig. D, taking either line as its right hand boundary).

A rectangle is a parallelogram whose angles are right angles (Fig. E).

A square is a rectangle whose four sides are all of equal length (Fig. F).

A triangle is any figure bounded by three straight lines (Fig. G, equilateral; Fig. H, right-angled).

An angle is produced at a given point by the meeting of two straight lines at that point (Fig. I, acute; Fig. J, obtuse; Fig. K, right-angled).

Adjacent angles are produced by the meetlng of three straight lines at a common point (as a point O in Fig. L).

The area of a piece of land is the amount of surface it contains expressed in square units.

LINES

A straight line has the same direction throughout.

A curved line has no part straight.

A broken line is composed of two or more different straight lines.

The length of a line is the number and kind of linear units it contains. Thus 4 feet may be the length of a line.

CIRCULAR MEASURE

To find circumference of a circle, multiply diameter by 3.1416.

To find diameter of circle, multiply circumference by .31831.

To find area of a circle, multiply square of diameter by .7854.

To find area of a triangle, multiply base by ½ perpendicular height.

MILL FACTORS

Mill factors means the number of board feet contained in the log, less the waste. Mill factor 8, indicates 8 board feet of lumber sawed, to 4 board feet wasted, in every cubic foot in the log. The waste in sawing depends on the following factors: Soundness of log; diameter of logs; thickness of saw; taper of logs; thickness of boards sawed; skill of sawyer; quality of machinery; shrinkage in drying. A good band saw mill will have a mill factor of 8, while a circular or rotary, about 7.

SOME THINGS A CRUISER SHOULD KNOW

How to select and read a compass.

The letters E and W on a large compass are reversed for convenience in reading.

The heavier and greater number of limbs are on the south side of a tree.

Moss grows on the north side of trees.

Small streams or brooks flow into larger ones and are the best guides out in case you are lost.

Not all standing trees are saw timber.

The number of rings, counting from the pith, is the only way one can tell the probable age of a tree. The size or thickness shows the growth each year.

Never go into the woods without a good reliable compass, a water-proof match box full of matches, and a good strong sheath or jack knife.

Never travel alone if you can avoid it; so many things could happen to you and a companion could go for assistance if nothing more.

The better care you take of yourself, the better and more work you can do

Don't think because you are in the woods that you must rough it as the Indians or woodsmen of fifty years ago did.

Have good plain food and a comfortable bed at night; no man can do good work who does not rest after turning in.

A machete is the best thing you can use for cutting through bushes or small trees.

The best way to determine the soundness of a standing tree is to spot or blaze a smooth place about as high as your head, then strike the blaze with back of axe; if it gives out a booming or hollow sound, you may feel sure it is bad part of the way up. One must train his ear to the sound as does a music teacher in pitching his tune.

In estimating the diameter of a standing tree, do not call a 12″ tree 16″. You know the full moon, when near the horizon, looks

the size of a cart wheel to some men, while to others only that of a tin plate. So be careful of your lengths and diameters.

Never scale a log above or just at the crotch, because it gives you a larger diameter; the length and top end give you amount of board feet in your log. The Doyle rule on small logs takes too many for a thousand feet, while on large logs the scale is so close they will barely squeeze through the mill. So be careful in using this rule. The Holland or Penobscot rule gives you nearer what you have in your log.

You can estimate 4 to 6 miles some days and in some countries, while other days and in other countries, one mile is a good day's work. Conditions of travel and amount of timber determine number of miles cruised.

Never trust to your memory in writing in your notes or at what point on your line the growth changed. At whatever point the change takes place or you encounter anything which should be noted, stop at that point and record it.

Keep your notes and estimates up with your work each day.

If you are an experienced cruiser and woodsman, and have for a companion a young man just out on his first real work from some school of forestry, don't laugh at the many new and seemingly foolish theories he has in his head. You can teach him more in one week about the real work in hand than he learned in all the years he was in school. If he has the right timber in him, of which woodsmen are made, he'll be grateful to you and think you are "Big Medicine." Talk to him and use him like a man and you'll learn some things from him you never dreamed of.

If you get lost, keep as cool-headed as you can. Don't run around. Sit down and talk it over with yourself. Give signals of distress and keep a good fire going at night.

PREPARING FOR A CRUISE

Never, if avoidable, go on a cruise in a rush. Make careful preparations and use good sound judgment in selecting your outfit. First, if possible, find out into what part of the country you are going, and what transportation facilities you will have. If transpor-

tation is other than your own back, a good many conveniences may be taken along which will add to your comfort and perhaps safety. If on the other hand, you have to pack everything, go carefully over your outfit and discard everything that is not absolutely needed. You will find, after this is done, that you have more than one man can carry comfortably. Where transportation is good, the following list of articles makes a good outfit:

One tent.
Water-proof knapsack.
Belt or pocket axe or macnete.
Pocket whetstone.
Small coil of rope.
Good wool blanket.
Rubber blanket.
Matches in tin water-proof box.
Steinfeld cot.
Suit good strong wool clothes.
2 Flannel outside shirts—blue or gray.
Pair extra pants—wool or khaki.
2 Suits underclothes.
Handkerchiefs.
Towels.
2 Pair wool or yarn stockings.
1 Short, light weight oil-coat.
1 Pair strong shoes.
1 Pair moccasins.
1 Pair leather or canvas leggings.
1 Soft hat of good quality.
1 Mosquito canopy made of cheese cloth.
1 Wool sweater.
1 Pair good heavy suspenders.
Belt.
Cake of toilet soap.
Cake of laundry soap.
Tooth brush.
Safety razor.
Good sheath or jack knife.
Water-proof match box.
Good reliable compass.
Canteen.
Pipes and tobacco.

Candles.
Strong fish line.
Half dozen assorted hooks.
Pencils.
Stationery.
Needles and thread.
Buttons.
A few copper rivets of different lengths.
Pins and safety pins.
Two-foot pocket rule.
Ball of yarn and darning needles.
Ditty bag to hold all your small articles.
Pocket comb or hair brush.

As part of this outfit will be worn it will lighten the pack.

A few home remedies for sickness and accidents: Keep your bowels open; a small bottle of compound cathartic pills will be found sufficient.

Sore throat—Remove your stocking and place it about your throat at night, also a little dry sulphur sprinkled in the throat; the inside bark of pine or cedar chewed.

Burns—Oil or common baking soda, dampened.

Cramps—Hot drinks of Jamaica ginger or pepper; piece of woolen cloth wrung out in hot water and laid over seat of pain.

Colds—Take repeated doses of quinine and keep warm and dry.

Ivy Poisoning—Take common soda and water and bathe parts affected; also solution of sugar of lead.

Poisoning—Induce vomiting by drinking large quantities of lukewarm water, or mustard and water.

Freezing—Keep moving. Don't fall asleep—it means death.

Drowning—Loosen all clothing; place the body face down with the head a little elevated; rub the body dry and keep warm. Draw the tongue forward and keep it there so it will not close the windpipe. Induce artificial respiration.

Lightning—Remove clothing and dash cold water over body. Keep this up for hours, if necessary.

Sore feet—Wash clean and rub bean grease into them before an open fire.

Fevers—Keep bowels open; doses of quinine; keep warm and dry; get to a doctor as soon as possible.

For black flies and mosquitoes—1 oz. castor oil, ½ oz. sweet oil, ¼ oz. oil of citronilla, ⅛ oz. aqua ammonia, 10 drops spirits camphor, 50 drops oil of pennyroyal. Mix and rub in lightly. Shake the bottle before using.

Sunstroke—Remove patient to shade; apply cold water or ice to head and neck; sponge body with cold water.

Snake or mad dog bite—Tie cord above wound and either cut the wound out or sear it with hot iron. Get patient to doctor at once.

Insect stings—Apply mud or fresh loam; salt and water, tincture iodine or weak ammonia.

Fainting—Lay flat on back, the head a little lower than the body; loosen clothing about neck and chest; bathe face and neck with cold water; have plenty of fresh air.

Cuts and wounds—Clean parts in pure water and wrap in bandage. Do not remove bandage for two or three days, unless the wound begins to have an offensive odor. A bottle of peroxide or a solution or carbolic acid are good antiseptics.

SPECIMEN PAGES

Pages 15, 16 and 17 are specimen pages filled in by the author to show the exact method of using the blank pages of this book for cruising record purposes. Page 15 represents the tree tally made upon the hinged tablet which lies upon the two pages of the book which are being used. This tablet is left narrow so as not to cover the two chain columns at the right of the page (page 16). The tablet also marks the working place in the book so that it may be returned to pocket, and when taken out again, quickly opened to the right place.

When the cruise of this mile strip is completed, the form on page 15 is added and its totals carried into the proper spaces on page 16. As this strip represents eight acres, a division of these quantities by eight gives the amounts per acre. These, in turn, are carried in summary to the bottom of the page to give the total per acre of all kinds of timber.

The cruising notes on page 17 will be found self explanatory, and the chain record in the two columns on page 16 refers to the corresponding details on the cruising line in the middle of page 17. Some useful symbols for the record have been listed at the bottom of page 17.

ESTimate 06 belong on page 16 LINE 1
